

## Econ 311: Behavioral and Experimental Economics

Prof. Jeffrey Naecker

Wesleyan University

1 / 10

### Motivating Evidence

- ▶ Recall dictator game from Forsythe et al (1994)
- ▶ What if we allow recipient to have some say in the matter?
  - ▶ 45 additional subjects drawn from same overall population
  - ▶ As before, one player proposes at division of a \$5 endowment
  - ▶ New treatment: recipient can either accept or reject the offer
  - ▶ If reject, they both get \$0
  - ▶ This is called the *ultimatum game*
- ▶ Expected results from classical preferences?

3 / 10

### Reciprocity

2 / 10

### Ultimatum Game: Responder Behavior

- ▶ Rejections do happen, though not very often
  - ▶ 8 out of 45 (18%) of offers were rejected in total
- ▶ Rejection likelihood increases as offers get smaller
  - ▶ No offers of \$2.50 (ie 50% of pie) or higher were rejected
  - ▶ 5 of 6 (83%) of offers less than \$2.00 were rejected
- ▶ Rejection is a form of *costly punishment*

4 / 10

## Ultimatum Game: Proposer Behavior

- ▶ Proposals below \$2.00 extremely rare
- ▶ Strong peak at \$2.50 (50-50 split)
- ▶ So in equilibrium, rejections are rare because low offers are rare

5 / 10

## Explaining Rejections

- ▶ Recall Fehr-Schmidt model from last lecture:

$$U(x_1, x_2) = \begin{cases} x_1 - \beta(x_2 - x_1) & \text{if } x_1 \leq x_2 \\ x_1 - \alpha(x_1 - x_2) & \text{if } x_1 > x_2 \end{cases}$$

where  $\alpha < \beta \leq 1$

- ▶ Let  $\beta = 1$  and  $\alpha = \frac{1}{2}$
- ▶ Player 1 is responder
- ▶ What is utility of rejecting?
- ▶ Will player 1 accept payoffs (\$2, \$3)?
- ▶ Will player 1 accept payoffs (\$1, \$4)
- ▶ So responder's desire for equity can lead to decision that decreases total welfare (aggregate payoffs)

6 / 10

## The Trust Game

- ▶ The ultimatum game is fairly limited in that it only allows the responder a binary choice: accept or punish
- ▶ What if we allow responder more variety in their choice, so they can not only punish, but also reward?
- ▶ The *trust game* accomplishes this
  - ▶ One player, the *trustor* starts out with  $\$X$
  - ▶ Passes some amount  $\$I \in [0, \$X]$  to other player, the *trustee* (so far, just like dictator/ultimatum)
  - ▶ Trustee gets  $R \cdot \$I$  for  $R > 1$ , ie the passed amount is multiplied by interest rate  $R$  before trustee receives it
  - ▶ Trustee then can return some amount  $\$P \in [0, R \cdot \$I]$  to trustor

7 / 10

## Trust Game: Evidence

- ▶ Berg et al (1995)
- ▶ Trustors start with \$10
- ▶ Trustors and trustees in different rooms
- ▶  $R = 3$ , ie if trustor passes \$1 it becomes \$3 for trustee
- ▶ Expected classical results?

8 / 10

## Trust Game: Results

9 / 10

## Trust Game: Discussion

- ▶ Did the average trustor make a profit by passing money to the trustee?
- ▶ Any limitations to design?
